

**5.1.1** How can I use exponential functions?

Applications of Exponential Functions

**#2** Julie has a fresh cup of hot coffee that has a temperature of  $180^{\circ}$  F. The temperature of the room is  $70^{\circ}$  F.

a. Sketch a graph of the temperature of the coffee over time.

b. Let  $t$  = number of minutes after Julie pours her coffee, and let  $y$  = the temperature of the coffee in  $^{\circ}$ F. Five minutes after Julie pours her coffee, its temperature is  $160^{\circ}$  F. Write an equation to model this situation.

c. What is the temperature of the coffee 15 minutes after it was poured? Justify your answer using the equation.

**#3** An important application of exponential functions lies in calculating the intensity of radiation from radioactive isotopes by using a mathematical model. Most isotopes emit particles and decay into stable forms. The amount of decay of the particles can be described by the isotope's **half-life**, which is the amount of time it takes half of the isotope to decay. For example, the half-life of Bromine-85 is 3 minutes. If you start with 60 g of Bromine-85, 3 minutes later 30 g will remain. How much Bromine-85 will remain after 20 minutes?

a. Estimate the answer.

b. Use the given information to write an equation that models the situation. (round your b-value/multiplier to the nearest 100th)

c. Use your equation to see how much bromine remains after 20min.
